Blank Quiz

Total points: 100

The respondent's email (2312369@gsuadder.kfu.ru) was recorded on submission.

1/1 Why is the dialect property important in hibernate.cfg.xml?

- It controls Java memory allocation for Hibernate.
- It specifies how Hibernate converts Java types to the database.
- It sets the default schema name.
- It determines the specific SQL variant Hibernate uses based on the database type.

Correct answer

- It determines the specific SQL variant Hibernate uses based on the database type.

1/1 What are the typical values for the hbm2ddl.auto property in hibernate.cfg.xml?

- auto, manual
- none, create, update, validate, create-drop
- start, stop
- true, false

Correct answer

- none, create, update, validate, create-drop

1/1 When should you use hbm2ddl.auto = none or omit this property?

When you want Hibernate to create the database schema every time.

When using an in-memory database only.

When you want Hibernate to drop tables after session ends.

When the database schema is managed externally and should not be changed by Hibernate.

Correct answer

When the database schema is managed externally and should not be changed by Hibernate.

1/1 What does hbm2ddl.auto = validate do?

Creates the database from entities automatically.

Deletes the schema after validation.

Validates the schema against entities on startup and throws an error if it mismatch, without modifying schema.

Updates the database schema to match entity definitions.

Correct answer

Validates the schema against entities on startup and throws an error if it mismatch, without modifying schema.

1/1 When calling the persist method on an entity, what kind of SQL query does Hibernate usually execute?

- SELECT statement to find the entity.
- An INSERT statement to save the new entity.
- An UPDATE statement to modify the entity.
- DELETE statement to remove the entity.

Correct answer

- An INSERT statement to save the new entity.

1/1 What query does Hibernate execute when you call the get method with the primary key of an entity?

- DELETE statement
- SELECT statement fetching the row by primary key
- INSERT statement
- UPDATE statement

Correct answer

- SELECT statement fetching the row by primary key

1/1 How does Hibernate determine which objects have a has-a (one-to-one or one-to-many) relationship and the corresponding database across tables?

By scanning for Java object classes only.

By analyzing foreign key annotations like @OneToOne and @ManyToMany and corresponding mapping metadata.

By querying based on table names.

It doesn't handle relationships; developer must write queries.

Correct answer

By analyzing foreign key annotations like @OneToOne and @ManyToMany and corresponding mapping metadata.

1/1 Which @Entity association cardinality and direction is implemented in the following code snippet?

```
@Entity
public class Yard {
@Id
private int yardNo;
@OneToOne(mappedBy="backYard")
private House house;
}

@Entity
public class House {
@Id
private int houseNo;
@OneToOne
private Yard backYard;
}
```

- @OneToOne bidirectional
- @OneToOne unidirectional
- @OneToOne bidirectional

Correct answer

- @OneToOne bidirectional

1/1 Which @Entity association cardinality and direction is implemented in the following code snippet?

Please choose only one answer:

```
@Entity
public class Window {
@Id
private int windowNo;
@OneToOne
private House house;
}

@Entity
public class House {
@Id
private int houseNo;
@OneToOne(mappedBy="house")
private List<Window> windows;
}
```

- @OneToOne bidirectional
- @OneToOne unidirectional
- @OneToOne no directional attribute specified
- @OneToOne bidirectional

Correct answer

- @OneToOne bidirectional

1/1 Which @Entity association cardinality and direction is implemented in the following code snippet?

Please choose only one answer:

```
@Entity
public class Yard {
@Id
private int yardNo;

@Entity
public class House {
@Id
private int houseNo;
@OneToOne(mappedBy="backYard")
private Yard backYard;
}
```

- @OneToOne bidirectional
- @OneToOne unidirectional
- @OneToOne no directional attribute specified
- @OneToOne bidirectional

Correct answer

- @OneToOne bidirectional

1/1 Please choose all the answers that apply:

```
@Entity
public class Window {
@Id
private int windowNo;
@OneToOne
private House house;
}

@Entity
public class House {
@Id
private int houseNo;
@OneToOne(mappedBy="house")
private List<Window> windows;
}
```

- The association owner is the Window class ✓
- The association owner is the House class
- It's OneToMany bidirectional association
- It's OneToMany unidirectional association

Correct answer

- It's OneToMany bidirectional association
- The association owner is the Window class

1/1 Please choose all the answers that apply:

```
@Entity
public class Yard {
@Id
private int yardNo;
@OneToOne(mappedBy="backYard")
private House house;
}

@Entity
public class House {
@Id
private int houseNo;
@OneToOne
private Yard backYard;
}
```

- It's OneToOne unidirectional association
- The association owner is the House class
- It's OneToOne bidirectional association
- The association owner is the Yard class

Correct answer

- It's OneToOne bidirectional association
- The association owner is the House class

1/1 Since no @GenerateValue annotation is present on the primary keys, how will Hibernate handle ID generation strategy by default?

- It will throw an error
- It will use GenerationType.IDENTITY automatically
- It expects the ID values to be assigned manually before persisting
- It will generate IDs using a database sequence

Correct answer

- It expects the ID values to be assigned manually before persisting

1/1 Given the absence of the @Table annotation on the entity classes, what default table names will Hibernate generate for the Yard and House entities, assuming default naming strategies?

- Yard and House (same as class names)
- YARD and HOUSE (uppercase)
- yard and house (all lowercase, since no explicit table name is specified)
- yard and House (lowercase entities, class)

1/1 If @Column annotations are not used, how will Hibernate name the columns for fields like yardNo and houseNo in PostgreSQL?

- uppercase (YARDNO)
- camelCase (yardNo)
- all lowercase concatenated (yardno)
- snake_case (yard_no)

Correct answer

- snake_case (yard_no)

1/1 If only the House entity is persisted (saved) to the database, will the associated Yard entity data be persisted automatically based on the above mapping?

- Yes, because the mappedBy side automatically persists both
- Yes, because the cascade option is not specified, you must persist Yard explicitly
- It depends on the generation type
- No, because the OneToOne association cascades automatically by default

Correct answer

- No, because the cascade option is not specified, you must persist Yard explicitly
